MANTA

The ocean makes the oxygen we breathe, and it is full of our plastic.

MANTA is a wave of it, made by an algorithm so you print only what you need.

THE STORY — OXYGEN, PLASTIC AND A WAVE

At least half of the oxygen we breathe comes from the ocean, so MANTA is a story of life: a wave that rose from the sea floor and stayed. Its feet hold the seabed like the fins of a manta, the ray that tells us how healthy the sea is; seen from the side, legs, seat and back draw an M, for Manta and for *Mare*. The colour is the depth of the water, deep blue at the feet to foam at the crest, where the ribbon breaks forward and falls back through itself; every seam is left white like spray, and the flutes follow the current.

Yet we fill that ocean with plastic; microplastics are now found even in human blood. And more and more of us, children too, print plastic at home. MANTA is plastic as well, so it is printed with sense: biomimicry puts material only where the load is, the parts need under 1 % of their filament as support, none trapped in a hole, and we recommend recycled PETG. A chair can carry that message and still be beautiful.

BIOMIMICRY — EVERY SECTION SIZED BY ITS LOAD

- **Wolff's law** — thickness follows the bending moment: 84 mm at the lumbar knot, 32 mm at the crest.
- **Murray's law** — the lumbar, the one true junction, is the cube-root-sum of its branches.
- **Spiral fibre** — flutes run along the stress path and stiffen by corrugation.
- **Shell** — the closed section and dished seat carry load as a shell.
- **Fiddlehead loop** — the crest returns through the backrest: a closed loop, not a cantilever.
- **Buttress roots** — forked feet: a wide stance from little material.

THE ALGORITHM — PRINT ONLY THE CHAIR YOU NEED

MANTA is generated by an algorithm written for it. Choose who the chair is for and how thick it is, and it rebuilds every cut, peg and joint, re-checks 15 load paths at 1.8 dynamic × 2.0 safety plus tipping, and refuses to export a chair that would fail. So anyone can print a lighter or a stronger MANTA, and only the plastic they need: the 70 kg version built here uses about half the filament of the 120 kg entry. At 120 kg: weakest glued check 2.1×, tipping 0.56 sideways and 0.55–0.77 rearward, 8/8 ergonomics checks. One command (manta_verify.py) re-checks it all: a **virtual assembly** of all 43 parts, bed fit, and the support PrusaSlicer really adds. No two of the 42 ribbon pieces are alike.

~250 kg	26×	~16.5 kg	~110 €
safe static load	glued full-section joint	finished weight	filament + epoxy

BUILT — COMPUTED JOINTS, PRINTED AT HOME

Cuts avoid the knee and lumbar, where bending peaks. Every joint is a full solid cross-section, epoxied and centred by a conical peg; the two most-loaded are pinned, and where the crest crosses the backrest it is glued on as a saddle. 43 parts, each ≤ 212 × 220 × 250 mm; PETG: ~16.5 kg, ~460 h, ~90 € filament + ~20 € epoxy. **A full-size prototype is printed and assembled** (light variant, 75 % walls) — photos on the board.
